

### Computer Architecture and Operating Systems Lecture 12: Basics of Networking

# Andrei Tatarnikov

atatarnikov@hse.ru @andrewt0301

# **Client-Server Architecture**

- Most network applications are based on the client-server model:
  - A server process and one or more client processes
  - Server manages some resource
  - Server provides service by manipulating resource for clients
  - Server activated by request from client (vending machine analogy)

Note: clients and servers are processes running on hosts (can be the same or different hosts)

# Hardware Organization of a Network Host

3

# **Computer Networks**

- A network is a hierarchical system of boxes and wires organized by geographical proximity
  - SAN (System Area Network) spans cluster or machine room
     Switched Ethernet, Quadrics QSW, ...
  - LAN (Local Area Network) spans a building or campus
    - Ethernet is most prominent example
  - WAN (Wide Area Network) spans country or world
    - Typically high-speed point-to-point phone lines
- An internetwork (internet) is an interconnected set of networks
  - The Global IP Internet (uppercase "I") is the most famous example of an internet (lowercase "i")
- Let us see how an internet is built from the ground up

## Lowest Level: Ethernet Segment

- Ethernet segment consists of a collection of *hosts* connected by wires (twisted pairs) to a *hub*
- Spans room or floor in a building
- Operation
  - Each Ethernet adapter has a unique 48-bit address (MAC address)
    - E.g., 00:16:ea:e3:54:e6
  - Hosts send bits to any other host in chunks called *frames*
  - Hub slavishly copies each bit from each port to every other port
    - Every host sees every bit
    - Note: Hubs are on their way out. Bridges (switches, routers) became cheap enough to replace them

# Next Level: Bridged Ethernet Segment

- Spans building or campus
- Bridges cleverly learn which hosts are reachable from which ports and then selectively copy frames from port to port

## **Conceptual View of LANs**

For simplicity, hubs, bridges, and wires are often shown as a collection of hosts attached to a single wire:

## Next Level: Internets

- Multiple incompatible LANs can be physically connected by specialized computers called *routers*
- The connected networks are called an *internet* (lower case)

LAN 1 and LAN 2 might be completely different, totally incompatible (e.g., Ethernet, Fibre Channel, 802.11\*, T1-links, DSL, ...)

# Logical Structure of Internet

#### Ad hoc interconnection of networks

- No particular topology
- Vastly different router & link capacities
- Send packets from source to destination by hopping through networks
  - Router forms bridge from one network to another
  - Different packets may take different routes

# The Notion of an Internet Protocol

- How is it possible to send bits across incompatible LANs and WANs?
- Solution: protocol software running on each host and router
  - Protocol is a set of rules that governs how hosts and routers should cooperate when they transfer data from network to network.
  - Smooths out the differences between the different networks

# What Does an internet Protocol Do?

#### Provides a naming scheme

- An internet protocol defines a uniform format for host addresses
- Each host (and router) is assigned at least one of these internet addresses that uniquely identifies it

#### Provides a delivery mechanism

- An internet protocol defines a standard transfer unit (*packet*)
- Packet consists of *header* and *payload* 
  - Header: contains info such as packet size, source and destination addresses
  - Payload: contains data bits sent from source host

#### Transferring Internet Data Via Encapsulation

12

# **Other Issues**

We are glossing over a number of important questions:

- What if different networks have different maximum frame sizes? (segmentation)
- How do routers know where to forward frames?
- How are routers informed when the network topology changes?
- What if packets get lost?

These (and other) questions are addressed by the area of systems known as *computer networking* 

# **Global IP Internet**

- Most famous example of an Internet
- Based on the TCP/IP protocol family
  - IP (Internet Protocol) :
    - Provides basic naming scheme and unreliable delivery capability of packets (datagrams) from host-to-host
  - UDP (Unreliable Datagram Protocol)
    - Uses IP to provide unreliable datagram delivery from process-to-process
  - TCP (Transmission Control Protocol)
    - Uses IP to provide *reliable* byte streams from *process-to-process* over *connections*

Accessed via a mix of Unix file I/O and functions from the sockets interface

# **Organization of an Internet Application**

# A Programmer's View of the Internet

1. Hosts are mapped to a set of 32-bit *IP addresses*128.2.203.179

2. The set of IP addresses is mapped to a set of identifiers called Internet *domain names* 

128.2.203.179 is mapped to www.cs.cmu.edu

3. A process on one Internet host can communicate with a process on another Internet host over a *connection* 

# Aside: IPv4 and IPv6

- The original Internet Protocol, with its 32-bit addresses, is known as Internet Protocol Version 4 (IPv4)
- 1996: Internet Engineering Task Force (IETF) introduced Internet Protocol Version 6 (IPv6) with 128-bit addresses
   Intended as the successor to IPv4
- As of 2015, vast majority of Internet traffic still carried by IPv4
  - Only 4% of users access Google services using IPv6.
- We will focus on IPv4, but will show you how to write networking code that is protocol-independent.

#### **IP Addresses**

32-bit IP addresses are stored in an IP address struct

- IP addresses are always stored in memory in *network byte order* (big-endian byte order)
- True in general for any integer transferred in a packet header from one machine to another.
  - E.g., the port number used to identify an Internet connection.

```
/* Internet address structure */
struct in_addr {
    uint32_t s_addr; /* network byte order (big-endian) */
};
```

## **Dotted Decimal Notation**

By convention, each byte in a 32-bit IP address is represented by its decimal value and separated by a period

IP address: 0x8002C2F2 = 128.2.194.242

•Use getaddrinfo and getnameinfo functions (described later) to convert between IP addresses and dotted decimal format.

#### **Internet Domain Names**

20

# **Domain Naming System (DNS)**

- The Internet maintains a mapping between IP addresses and domain names in a huge worldwide distributed database called DNS
- Conceptually, programmers can view the DNS database as a collection of millions of *host entries*.
  - Each host entry defines the mapping between a set of domain names and IP addresses.
  - In a mathematical sense, a host entry is an equivalence class of domain names and IP addresses.

# **Properties of DNS Mappings**

Can explore properties of DNS mappings using nslookup

Output edited for brevity

linux> nslookup localhost

Address: 127.0.0.1

Each host has a locally defined domain name localhost which always maps to the loopback address 127.0.0.1

linux> hostname

whaleshark.ics.cs.cmu.edu

■Use hostname to determine real domain name of local host:

# **Properties of DNS Mappings**

# Simple case: one-to-one mapping between domain name and IP address:

linux> nslookup whaleshark.ics.cs.cmu.edu
Address: 128.2.210.175

# Multiple domain names mapped to the same IP address:

linux> nslookup cs.mit.edu
Address: 18.62.1.6
linux> nslookup eecs.mit.edu
Address: 18.62.1.6

# **Properties of DNS Mappings**

# Multiple domain names mapped to multiple IP addresses:

linux> nslookup www.twitter.com
Address: 199.16.156.6
Address: 199.16.156.70
Address: 199.16.156.102
Address: 199.16.156.230

linux> nslookup twitter.com
Address: 199.16.156.102
Address: 199.16.156.230
Address: 199.16.156.6
Address: 199.16.156.70

#### Some valid domain names don't map to any IP address:

linux> nslookup ics.cs.cmu.edu

\*\*\* Can't find ics.cs.cmu.edu: No answer

### **Internet Connections**

Clients and servers communicate by sending streams of bytes over connections. Each connection is:

- Point-to-point: connects a pair of processes.
- Full-duplex: data can flow in both directions at the same time,
- Reliable: stream of bytes sent by the source is eventually received by the destination in the same order it was sent.
- A socket is an endpoint of a connection
   Socket address is an IPaddress:port pair
- A *port* is a 16-bit integer that identifies a process:
  - Ephemeral port: Assigned automatically by client kernel when client makes a connection request.
  - Well-known port: Associated with some service provided by a server (e.g., port 80 is associated with Web servers)

# Well-known Ports and Service Names

Popular services have permanently assigned well-known ports and corresponding well-known service names:

- echo server: 7/echo
- ssh servers: 22/ssh
- email server: 25/smtp
- Web servers: 80/http

 Mappings between well-known ports and service names is contained in the file /etc/services on each Linux machine.

# Anatomy of a Connection

A connection is uniquely identified by the socket addresses of its endpoints (*socket pair*)
 (cliaddr:cliport, servaddr:servport)

# **Using Ports to Identify Services**

28

#### **Basic Internet Components**

Internet backbone:

 collection of routers (nationwide or worldwide) connected by highspeed point-to-point networks

- Internet Exchange Points (IXP):
  - router that connects multiple backbones (often referred to as peers)
  - Also called Network Access Points (NAP)
- Regional networks:
  - smaller backbones that cover smaller geographical areas (e.g., cities or states)
- Point of presence (POP):
  - machine that is connected to the Internet
- Internet Service Providers (ISPs):
  - provide dial-up or direct access to POPs

#### **Internet Connection Hierarchy**

# **IP Address Structure**

#### IP (V4) Address space divided into classes:

- Network ID Written in form w.x.y.z/n
  - n = number of bits in host address
  - E.g., CMU written as 128.2.0.0/16
    - Class B address
- Unrouted (private) IP addresses: 10.0.0/8 172.16.0.0/12 192.168.0.0/16

# Any Questions?

	.text
start	: addi t1, zero, 0x18
	addi t2, zero, 0x21
